Assignment 2: Report

GitHub: <https://github.com/Dominic-Um>, <https://github.com/noamvardi>

Project: Marble

Description of implementation:

We implemented the marble physics using rigidbody and a repurposed version of the player movement script from assignment 1. The checkpoints are also implemented as they were in Assignment 1. The camera has a script that follows and focuses on the marble depending on the marbles' movement using transform. The player respawns are handled through planes with trigger colliders to detect if the player has fallen off the map. We have a moving obstacle that has a script that moves it back and forth in both directions in a selectable range and speed.

Reflection (Dominic): I implemented the camera script as well as the respawn system. The camera script taught me about how important perspective is for the player and how to balance functionality of the camera and player experience. I learned how difficult it can be to make a camera that smoothly follows the marble and how much of it is trial and error. For the respawn system, I learned about how to handle edge cases better and how much thought goes into designing player failure states, in particular making it working in conjunction with the spawn points helped me to develop my scripting skills in Unity.

Reflection (Noam): I implemented the marble movement and the moving obstacle- It was interesting to see how you can re-use and learn from previous development experience as I did

here from Assignment 1. I think I also prioritized ease of access to many of the functions available, such as selecting the moving radius of the moving obstacle- through public variables and the unity editor.
